(54) Title: CHARACTER DISPLAY APPARATUS AND CHARACTER DISPLAY METHOD, CONTROL PROGRAM FOR CONTROLLING THE CHARACTER DISPLY METHOD AND RECORDING MEDIUM RECORDING THE CONTROL PROGRAM

(57) Abstract: A character display apparatus is provided, which comprises a display device comprising a plurality of pixels, and a control section for controlling the display device. Each of the plurality of pixels comprises a plurality of sub-pixels arranged in a predetermined direction. A first pixel of the plurality of pixels comprises a plurality of first sub-pixels. At least one pixel neighboring the first pixel comprises a plurality of second sub-pixels. The control section determines an arrangement pattern containing a plurality of elements, in which a value of each of the plurality of elements is determined depending on whether or not a basic portion indicating a skeleton of a character is assigned to a corresponding sub-pixel of the plurality of the first and second sub-pixels. The control section determines a luminance level of the first pixel based on the arrangement pattern.

DESCRIPTION

CHARACTER DISPLAY APPARATUS AND CHARACTER DISPLAY METHOD,
CONTROL PROGRAM FOR CONTROLLING THE CHARACTER DISPLAY METHOD

5 AND RECORDING MEDIUM RECORDING THE CONTROL PROGRAM

TECHNICAL FIELD

10 The present invention relates to a character display
apparatus and method capable of displaying characters with
a high resolution using a color display device. The present
invention also relates to a control program for controlling
the character display method and a recording medium in which
the control program is recorded.

15

BACKGROUND ART

20 Some personal computers, word processors, mobile
telephones comprise a display section capable of displaying
color. As a technique for displaying characters with a high
resolution in such apparatuses, for example, Japanese
Laid-Open Publication No. 2001-100725 discloses a character
display apparatus.

This character display apparatus is provided with a plurality of pixels on a display surface thereof. Each pixel comprises a plurality of sub-pixels arranged in a predetermined direction, to which respective colors (e.g.,
5 Red (R), Green (G), and Blue (B)) are assigned. The strength of a color element in a sub-pixel is represented by the level of the color element which has a plurality of steps, e.g., 0 to 7. If a certain level of color element is assigned to a sub-pixel corresponding to the skeleton of a character,
10 color element levels which vary stepwise around the sub-pixel are assigned to surrounding sub-pixels. The color element levels are arranged in a predetermined pattern. Each color element level is converted to a luminance level in accordance with predetermined correspondence.

15

The level of a color element corresponds to the degree of the color element which contributes to the color of a character. The greater the contribution of a sub-pixel to the color of a character, the greater the color element level
20 of the sub-pixel. The greater the contribution of a sub-pixel to the color of a background, the lower the color element level of the sub-pixel. The luminance level of a sub-pixel corresponds to the degree of light emission of the sub-pixel. The greater the luminance level of a sub-pixel, the greater

the degree of light emission of the sub-pixel. The lower the luminance level, the lower the degree of light emission. Thus, by controlling the color element level on a sub-pixel-by-sub-pixel basis so as to display the shapes of characters, the characters can be displayed with a higher resolution than when the luminance level is controlled on a pixel-by-pixel basis. Further, by forming a pattern of color element levels which vary stepwise around a sub-pixel corresponding to the skeleton of a character, color noise can be suppressed.

Japanese Laid-Open Publication No. 2001-184051 discloses another character display apparatus capable of displaying characters with a high resolution. In this character display apparatus, a predetermined correspondence between the above-described color element level and luminance level is appropriately changed according to the color of a character to be displayed and the color of a background. As a result, characters can be displayed with a high resolution in any character color and any background color.

Figure 12 is a block diagram showing a representative configuration of a character display apparatus 1a as disclosed in Japanese Laid-Open Publication

Nos. 2001-100725 and 2001-184051 described above.

Examples of the character display apparatus 1a include any information display apparatuses comprising a display device capable of displaying color, such as electronic apparatuses, information apparatuses, and the like, specifically personal computers and word processors of any type, such as desktop, laptop, and the like. Examples of the character display apparatus 1a also include electronic apparatuses comprising a color liquid crystal display device, such as communication apparatuses (e.g., personal digital assistants, mobile telephones including PHS, general fixed telephones, FAX, etc.).

The character display apparatus 1a comprises a display device 3. The display device 3 is capable of displaying color. Examples of the display device 3 include liquid crystal displays, organic EL displays, and the like.

The display device 3 is connected to a control section 20. The control section 20 comprises a CPU 2 and a main memory 4. The control section 20 separately controls a plurality of color elements corresponding to a plurality of sub-pixels included in the display device 3. The control

section 20 is connected to an input device 7 and an auxiliary memory apparatus 40.

5 The input device 7 is an apparatus for inputting characters to be displayed on the display device 3, instructions of the user, and the like. Examples of the input device 7 include keyboards, touch panels, mice, and the like.

10 The auxiliary memory apparatus 40 stores a display program 41a for displaying characters, and data 5 including character shape data 5b, a correction table 5c and a luminance table 5d. Examples of the character shape data 5b include outline data representing the contour shapes of characters, skeleton data representing the skeletal shapes
15 of characters, bitmap data representing characters, and the like. Note that processing by the display program 41a slightly varies depending on the type of the character shape data 5b. Characters to be displayed may include simple graphics, such as pictographic characters and the like. In
20 the descriptions below, characters are illustrated.

 The correction table 5c is used to determine the color element levels of sub-pixels neighboring a sub-pixel corresponding to a basic portion. For example, when the color

element level of a sub-pixel corresponding to a basic portion is 7, the color element levels of its neighboring sub-pixels are set to be, for example, 5, 2 and 1 from the nearest to the basic portion. The luminance table 5d defines a
5 correspondence between color element levels and luminance levels.

Figures 13A and 13B are diagrams for explaining a display surface of the display device 3. The display surface
10 of the display device 3 is provided with a plurality of pixels 10 for displaying characters, graphics, and the like as shown in Figure 13A. Each pixel 10 comprises 3 sub-pixels 11 arranged in a predetermined direction (a horizontal direction in Figure 13A), to which respective
15 color elements (e.g., Red (R), Green (G), and Blue (B)) are assigned.

When a character is displayed on the display surface, the basic portion representing the skeleton of the character
20 is assigned to sub-pixels 11 in pixels 10 associated with the character according to the character shape data 5b. For example, when a Kanji character "忙" is displayed, the basic portion corresponding to the skeleton of the character is assigned to sub-pixels 11 indicated by hatched portions shown

in Figure 9.

A process for associating the basic portion representing the skeleton of a character with sub-pixels 11 varies depending on the type of the character shape data 5b. For example, outline data contains a character code for identifying the type of a character, the number of strokes constituting a single character (the stroke count of a character), the number of contour points constituting a single stroke, the coordinates of contour points constituting a single stroke, and the like. In this case, each stroke has a shape enclosed by a contour line approximated by curved lines, straight lines, arcs, a combination thereof, or the like, and a predetermined thickness so as to display the contour shape of a character. A contour line representing the contour shape of a character can be approximated by straight lines, curved lines, arcs, a combination thereof, or the like, using the coordinate data of contour points. If an area where the inside of a contour line overlaps a sub-pixel is greater than or equal to a predetermined area, such a sub-pixel is determined to correspond to a basic portion representing the skeleton of a character.

Skeleton data contains a character code for

identifying the type of a character, the number of strokes constituting a single character, the number of points constituting a single stroke, the line type of a stroke (curved line, straight line, or the like), the coordinates of points constituting a single stroke, and the like. In this case, each stroke is in the form of a line of a certain line type for representing the skeletal shape of a character, and does not have a thickness. If the line type of a stroke is a straight line, the stroke can be approximated by a straight line passing through a plurality of points constituting the stroke using the coordinate data. If the line type of a stroke is a curved line, the stroke can be approximated by a curved line passing through a plurality of points constituting the stroke using the coordinate data. Sub-pixels 11 on a stroke are determined as sub-pixels 12 (Figure 13) corresponding to the basic portion representing the skeleton of a character.

When a sub-pixel 12 corresponding to the basic portion representing the skeleton of a character is determined, the color element levels of the sub-pixel 12 and a sub-pixel 13 neighboring the sub-pixel 12 are determined. For example, when a sub-pixel 12 (hatched in Figure 13B), which is located at the middle of three sub-pixels 11 (Figure 13A) constituting a pixel 10, is

determined to correspond to a basic portion, the color element level of the sub-pixel 12 corresponding to the basic portion is set to be "7" which is the maximum level. The color element levels of sub-pixels 13 which neighbor the sub-pixel 12 corresponding to the basic portion and are determined not to correspond to the basic portion, are set according to the correction table 5C whose example is shown in Figure 10. For example, when a correction pattern 1 is selected, the color element levels of the sub-pixels 13 which neighbor the sub-pixel 12 corresponding to the basic portion, are set to be stepwise decreased, e.g., "5", "2", and "1" with an increase in the distance from the sub-pixel 12 corresponding to the basic portion. Alternatively, when a correction pattern 2 is selected, the color element levels of the sub-pixels 13 which neighbor the sub-pixel 12 corresponding to the basic portion, are set to be stepwise decreased, e.g., "5", "2", and "1" with an increase in the distance from the sub-pixel 12 corresponding to the basic portion. The color element level of sub-pixels 14, which are located at a distance of four pixels from the sub-pixel 12 corresponding to the basic portion, is set to be "0" which is intended to represent a background.

Note that when a sub-pixel 13, which does not

correspond to a basic portion, neighbors a plurality of sub-pixels 12 corresponding to a basic portion, the color element level of the sub-pixel 13 can take a plurality of values depending on the distance from the sub-pixels 12.

5 In this case, the color element level of the sub-pixel 13 is set to be the greatest value.

The color element level of each sub-pixel is converted to a luminance level according to a correspondence between
10 color element levels and luminance levels defined in the luminance table 5d whose example is shown in Figure 11. In Figure 13B, the luminance level of the sub-pixel 12 corresponding to the basic portion is set to be "0". The luminance level of a sub-pixel having a color element level
15 of "5", which neighbors the sub-pixel 12, is set to be "73". The luminance level of a sub-pixel having a color element level of "2" is set to be "182". The luminance level of a sub-pixel having a color element level of "1" is set to be "219". The luminance level of the sub-pixel 14, whose color
20 element level is set to "0" as a background, is set to be "255".

Figure 14 is a flowchart indicating a process flow of the display program 41a (Figure 12) when the character

shape data 5b is skeleton data.

In step S1, a character code and a character size are input through the input device 7. For example, when a
5 Kanji character "木" is displayed on the display device 10,
4458 (JIS KUTEN code, 44th section and 58th point) is input
as a character code. The character size is represented by
the number of dots in a horizontal direction and the number
of dots in a vertical direction, e.g., 20 dots x 20 dots,
10 for example.

In step S2, skeleton data corresponding to the input
character code is read from the character shape data 5b in
the auxiliary memory apparatus 40 and is then stored in the
15 main memory 4 of the control apparatus 20. This skeleton
data contains a character code for identifying the type of
a character, the number of strokes constituting a single
character, the number of points constituting a single stroke,
the line type of a stroke, the coordinates of points
20 constituting a single stroke, and the like.

In step S3, the coordinate data of points
constituting each stroke is scaled according to the character
size input through the input device 7. This scaling converts

the coordinate data in the skeleton data defined in a predetermined coordinate system to a real pixel coordinate system for the display device 10. In this case, the scaling is performed by considering the arrangement of sub-pixels.

5 As shown in Figure 13A, for example, one pixel 10 comprises three sub-pixels 11 arranged in an X direction. When a character size is 20 dots x 20 dots, the coordinate data of the skeleton data is scaled into data of 60(=20x3) pixels x 20 pixels.

10

In step S4, the coordinate data of points constituting a stroke is obtained. In step S5, it is determined whether the type of stroke is a straight line or a curved line from the line type of the stroke contained
15 in the skeleton data. When the type of stroke is a straight line, the process goes to step S6. When the type of stroke is a curved line, but not a straight line, the process goes to step S7.

20

In step S6, the points constituting the stroke are linked with straight lines, and sub-pixels on the straight lines are defined as the basic portion representing the skeleton of a character. In step S7, the coordinate data of the points constituting the stroke is approximated by

curved lines, and sub-pixels positioned on the curved lines are defined as the basic portion representing the skeleton of a character.

5 In step S8, the color element level of the sub-pixel corresponding to the basic portion representing the skeleton of the character, which is defined in step S6 or step S7, is set to be "7" which is the maximum color element level. Next, in step S9, the color element levels of sub-pixels
10 neighboring the sub-pixel corresponding to the basic portion are set according to the correction table 5c.

 In step S10, it is determined whether or not all strokes contained in a character have been processed. If
15 "Yes", the process goes to step S11. If "No", the process returns to step S3 and is continued. In step S11, the color element levels of the sub-pixels are converted to respective luminance levels according to the luminance table 5d indicating the correspondence between color element levels
20 and luminance levels. In step S12, luminance data indicating the luminance levels of the sub-pixels determined in step S11 is transferred to the display device 3.

 In this manner, luminance levels are adjusted on a

sub-pixel-by-sub-pixel basis to display a character on the display device 3. In this case, sub-pixels corresponding to the basic portion representing the skeleton of a character are obtained from the skeleton data. Alternatively, such
5 sub-pixels may be obtained from outline data, bitmap data, or the like by a predetermined process. Alternatively, the pattern of the basic portion may be previously stored as character shape data in the auxiliary memory apparatus 40 and may be read as required.

10

In the above-described conventional technique, a pattern of the color element levels of sub-pixels constituting a character is determined, and thereafter, the color element levels are converted to respective luminance
15 levels which are actually displayed on a display section. Therefore, the process is complicated and a working memory area required for the process is increased. As a result, character display processing is slowed, the hardware cost is increased, and the like.

20

In the above-described conventional technique, when two or more strokes having a predetermined width are near to or cross each other, the space portion within a character is reduced so that the shape of the character is hardly

recognized, i.e., "deformed character". To avoid this, a pattern of the color element levels of sub-pixels is changed. However, it is a complicated task to change a pattern of color element levels by actually recognizing the positional
5 relationship between strokes.

When colors can be arbitrarily assigned to characters and backgrounds to be displayed, some combination of the color of a character and the color of a background may not
10 be suitable for a pattern of color element levels, resulting in a degradation in the shape of a character and a significant reduction in the visibility of the character.

15

DISCLOSURE OF THE INVENTION

According to one aspect of the present invention, a character display apparatus comprises a display device comprising a plurality of pixels, and a control section for
20 controlling the display device. Each of the plurality of pixels comprises a plurality of sub-pixels arranged in a predetermined direction, and at least one of a plurality of color elements is assigned to each of the plurality of sub-pixel. The control section determines at least one

sub-pixel, to which a basic portion indicating a skeleton of a character is assigned, among the plurality of sub-pixels in the display device, based on character shape data indicating character shapes. A first pixel of the plurality
5 of pixels comprises a plurality of first sub-pixels. At least one pixel neighboring the first pixel comprises a plurality of second sub-pixels. The control section determines an arrangement pattern containing a plurality of elements, in which a value of each of the plurality of elements is determined
10 depending on whether or not the basic portion is assigned to a corresponding sub-pixel of the plurality of the first sub-pixels and the plurality of the second sub-pixels. The control section determines a luminance level of the first pixel based on the arrangement pattern.

15

In one embodiment of this present invention, the plurality of elements include a first element and a second element neighboring the first element. A value of the first element indicates that the basic portion is assigned to a
20 sub-pixel relating to the first element. A value of the second element indicates that the basic portion is not assigned to a sub-pixel relating to the second element. The control section determines the luminance level of the first pixel based on another arrangement pattern which is modified

from said arrangement pattern such that a value of the first element is interchanged with a value of the second element.

In one embodiment of this invention, the plurality
5 of elements include a first element and a second element
neighboring the first element. A value of the first element
indicates that the basic portion is assigned to a sub-pixel
relating to the first element. A value of the second element
indicates that the basic portion is not assigned to a sub-pixel
10 relating to the second element. The control section
determines the luminance level of the first pixel based on
another arrangement pattern which is modified from said
arrangement pattern such that a value of the second element
is changed to indicate that the basic pattern is assigned
15 to the sub-pixel relating to the second element.

In one embodiment of this invention, the control
section determines the luminance level of the first pixel
based on a combination of a color of the character and a
20 background color of the character and the arrangement
pattern.

In one embodiment of this invention, the control
section compares a combination of a color of the character

and a background color of the character with a combination
of a predetermined character color and a predetermined
background color, and determines the luminance level of the
first pixel based on a result of the comparison and the
5 arrangement pattern.

According to another aspect of the present invention,
a method for displaying a character on a character display
apparatus is provided. The character display apparatus
10 comprises a display device comprising a plurality of pixels
and a control section for controlling the display device.
Each of the plurality of pixels comprises a plurality of
sub-pixels arranged in a predetermined direction, and at
least one of a plurality of color elements is assigned to
15 each of the plurality of sub-pixel. A first pixel of the
plurality of pixels comprises a plurality of first sub-pixels.
At least one pixel neighboring the first pixel comprises
a plurality of second sub-pixels. The method comprises the
steps of determining at least one sub-pixel, to which a basic
20 portion indicating a skeleton of a character is assigned,
among the plurality of sub-pixels in the display device,
based on character shape data indicating character shapes,
determining an arrangement pattern containing a plurality
of elements, in which a value of each of the plurality of

elements is determined depending on whether or not the basic portion is assigned to a corresponding sub-pixel of the plurality of the first sub-pixels and the plurality of the second sub-pixels, and determining a luminance level of the first pixel based on the arrangement pattern.

According to another aspect of the present invention, a program for causing a character display apparatus to execute a character display process is provided. The character display apparatus comprises a display device comprising a plurality of pixels and a control section for controlling the display device. Each of the plurality of pixels comprises a plurality of sub-pixels arranged in a predetermined direction, and at least one of a plurality of color elements is assigned to each of the plurality of sub-pixel. A first pixel of the plurality of pixels comprises a plurality of first sub-pixels. At least one pixel neighboring the first pixel comprises a plurality of second sub-pixels. The character display process comprises the steps of determining at least one sub-pixel, to which a basic portion indicating a skeleton of a character is assigned, among the plurality of sub-pixels in the display device, based on character shape data indicating character shapes, determining an arrangement pattern containing a plurality of elements, in which a value

of each of the plurality of elements is determined depending on whether or not the basic portion is assigned to a corresponding sub-pixel of the plurality of the first sub-pixels and the plurality of the second sub-pixels, and
5 determining a luminance level of the first pixel based on the arrangement pattern.

According to another aspect of the present invention, a recording medium storing a program for causing a character
10 display apparatus to execute a character display process is provided. The recording medium is readable by the character display apparatus. The character display apparatus comprises a display device comprising a plurality of pixels and a control section for controlling the display
15 device. Each of the plurality of pixels comprises a plurality of sub-pixels arranged in a predetermined direction, and at least one of a plurality of color elements is assigned to each of the plurality of sub-pixel. A first pixel of the plurality of pixels comprises a plurality of first sub-pixels.
20 At least one pixel neighboring the first pixel comprises a plurality of second sub-pixels. The character display process comprises the steps of determining at least one sub-pixel, to which a basic portion indicating a skeleton of a character is assigned, among the plurality of sub-pixels

in the display device, based on character shape data indicating character shapes, determining an arrangement pattern containing a plurality of elements, in which a value of each of the plurality of elements is determined depending on whether or not the basic portion is assigned to a corresponding sub-pixel of the plurality of the first sub-pixels and the plurality of the second sub-pixels, and determining a luminance level of the first pixel based on the arrangement pattern.

10

Functions of the present invention will be described below.

According to the present invention, the display surface of the display section is provided with a plurality of pixels each containing a plurality of sub-pixels arranged in a predetermined direction. At least one of a plurality of color elements is assigned to each sub-pixel. When displaying a character on the display surface of the display section, sub-pixels corresponding to the basic portion representing the skeleton of a character are determined from the sub-pixels based on character shape data representing the shapes of characters, such as skeleton data representing the skeletal shapes of characters, outline data representing

15
20

the contour shapes of characters, bitmap data representing characters, or the like. The arrangement pattern of sub-pixels in a pixel whose luminance level is to be determined and its neighboring sub-pixels are determined. Based on the arrangement pattern of sub-pixels, the luminance levels of sub-pixels contained in the pixel are determined. The luminance levels of all pixels in the display surface are determined in this manner so that the character is displayed on the display section.

10

Therefore, when displaying characters with high resolution and high definition, luminance levels can be determined only by extracting arrangements of sub-pixels corresponding to a basic portion (as used herein, the term "arrangement of sub-pixels corresponding to a basic portion" indicates an arrangement of sub-pixels each corresponding to a basic portion or a non-basic portion of a character). Therefore, processes can be simplified and the processes can be performed at practical speed even using a CPU having a low processing speed, as compared to a conventional technique in which the color element level of a sub-pixel corresponding to a basic portion and the color element levels of sub-pixels neighboring that sub-pixel are determined before the color element levels are used to determine the

20

color luminance level of a pixel of interest. Further, the size of a control program describing a procedure can be reduced, thereby making it possible to reduce the size of an auxiliary memory apparatus. Furthermore, the simplification of processes can reduce a working memory region required during processing. As a result, the cost of a character display apparatus can be reduced, thereby making it possible to realize a character display with high resolution and high definition.

10

According to the present invention, when the luminance levels of sub-pixels contained in a pixel of interest are determined based on the arrangement of sub-pixels corresponding to a basic portion, the position of a sub-pixel corresponding to a basic portion is replaced with its neighboring sub-pixel, and the arrangement of sub-pixels including such a replacement is used to determine the luminance levels of sub-pixels contained in a pixel of interest. Therefore, when sub-pixels corresponding to the skeleton of a character are close to each other, the arrangement of sub-pixels can be changed so that such sub-pixels are spaced to a further distance. Thereby, it is possible to prevent space within a character from being diminished to deform the character when strokes of the

15

20

character are close to each other. The arrangement of sub-pixels corresponding to the skeleton of a character may not be suitable for the shape of the character, depending on a color combination of a character and a background. Even
5 in this situation, by changing the arrangement of sub-pixels corresponding to the skeleton, distortion of the character can be corrected.

According to the present invention, when the
10 luminance levels of sub-pixels contained in a pixel of interest is determined based on the arrangement of sub-pixels corresponding to a basic portion, a sub-pixel corresponding to a basic portion is duplicated and provided to its neighboring sub-pixel. The arrangement of sub-pixels
15 including the duplicate sub-pixels can be used to determine the luminance levels of sub-pixels contained in a pixel of interest. Thus, a sub-pixel corresponding to the skeleton of a character can be multiplexed, thereby making it possible to simplify a process of thickening the line width of a
20 character so that the process can be efficiently performed.

According to the present invention, when the luminance levels of sub-pixels contained in a pixel of interest are determined based on the arrangement of

sub-pixels corresponding to a basic portion, the correspondence between the arrangement of sub-pixels and the luminance levels of sub-pixels contained in a pixel of interest can be changed depending on a combination of a character color and a background color. Therefore, the optimum luminance levels of sub-pixels contained in a pixel of interest can be determined depending on a character color and a background color. Therefore, characters having an optimum linewidth can be displayed for each color combination, whereby characters can be displayed with a high level of visibility irrespective of a color combination.

According to the present invention, when the luminance levels of sub-pixels contained in a pixel of interest are determined based on the arrangement of sub-pixels corresponding to a basic portion, the correspondence between the arrangement of sub-pixels and the luminance levels of sub-pixels contained in a pixel of interest can be changed according to the size of the difference between character and background colors previously registered and character and background colors to be displayed. The above-described correspondence can be shared by a group of characters having similar color combinations (similar luminance levels of sub-pixels),

whereby characters can be displayed with a more variety of color combinations and an optimum line width while suppressing the storage capacity of a character display apparatus to a small level.

5

Thus, the invention described herein makes possible the advantages of (1) providing a character display apparatus and method capable of displaying characters with a high resolution and definition by a simple process, wherein the speed of character display processing is increased and the hardware cost can be decreased; (2) a control program for controlling the character display method; and a recording medium in which the control program is stored.

10

15

These and other advantages of the present invention will become apparent to those skilled in the art upon reading and understanding the following detailed description with reference to the accompanying figures.

BEST MODE FOR CARRYING OUT THE INVENTION

Hereinafter, the present invention will be described by way of illustrative examples with reference to the accompanying drawings.

20

Figure 1 is a block diagram showing a configuration of a character display apparatus according to an embodiment

of the present invention. Examples of the character display apparatus 1b include any information display apparatuses comprising a display device capable of displaying color, such as electronic apparatuses, information apparatuses, and the like, specifically personal computers and word processors of any type, such as desktop, laptop, and the like. Examples of the character display apparatus 1b also include electronic apparatuses comprising a color liquid crystal display device, such as communication apparatuses (e.g., personal digital assistants, mobile telephones including PHS, general fixed telephones, FAX, etc.).

The character display apparatus 1b comprises a display device 3 comprising a plurality of pixels. The display device 3 is capable of displaying color. Examples of the display device 3 include liquid crystal displays, organic EL displays, and the like.

The display device 3 is connected to a control section 20. The control section 20 controls the operation of the display device 3. The control section 20 comprises a CPU 2 and a main memory 4. The control section 20 separately controls a plurality of color elements corresponding to a plurality of sub-pixels included in the

display device 3. The control section 20 is connected to an input device 7 and an auxiliary memory apparatus 40.

5 The input device 7 is an apparatus for inputting characters to be displayed on the display device 3, instructions of the user, and the like. Examples of the input device 7 include keyboards, touch panels, mice, and the like.

10 The auxiliary memory apparatus 40 stores a display program 41b for displaying characters and data 5 containing character shape data 5b and a pixel value table 5e. A recording medium 8 (e.g., an optical disc), which is readable by the character display apparatus 1b, stores the display program 41b and the data 5. The display program 41b and the data 5 may be installed from the recording medium 8 to the auxiliary memory apparatus 40 or may be previously stored in the auxiliary memory apparatus 40. Examples of the character shape data 5b include outline data representing the contour shapes of characters, skeleton data representing the skeletal shapes of characters, bitmap data representing characters, and the like. Note that processing by the display program 41b slightly varies depending on the type of the character shape data 5b. Characters to be displayed may include simple graphics, such as pictographic characters

15

20

and the like. In descriptions below, characters are illustrated.

The pixel value table 5e contains a correspondence
5 between the arrangement pattern of a basic portion comprising
M+2×N sub-pixels (M sub-pixels contained in a pixel (pixel
of interest) whose luminance level is determined and N
sub-pixels neighboring each side of the M sub-pixels), and
the luminance levels (pixel value) of the M sub-pixels of
10 the pixel of interest.

Figures 2A to 2C are diagrams for explaining a display
surface of the display device 3. The display surface of the
display device 3 is provided with a plurality of pixels 10
15 for displaying characters, graphics, and the like as shown
in Figure 2A. Each pixel 10 comprises 3 sub-pixels 11
arranged in a predetermined direction (a horizontal direction
in Figure 2A), to each of which at least one color element
(e.g., Red (R), Green (G), and Blue (B)) is assigned.

20

When a character is displayed on the display surface,
the basic portion representing the skeleton of the character
is assigned to sub-pixels 11 in pixels 10 associated with
the character according to the character shape data 5b. For

example, when a Kanji character "竹" is displayed, the basic portion corresponding to the skeleton of the character is assigned to sub-pixels 11 indicated by hatched portions shown in Figure 9.

5

A process for associating the basic portion representing the skeleton of a character with sub-pixels 11 varies depending on the type of the character shape data 5b. For example, outline data contains a character code for identifying the type of a character, the number of strokes constituting a single character (the stroke count of a character), the number of contour points constituting a single stroke, the coordinates of contour points constituting a single stroke, and the like. In this case, each stroke has a shape enclosed by a contour line approximated by curved lines, straight lines, arcs, a combination thereof, or the like, and a predetermined thickness so as to display the contour shape of a character. A contour line representing the contour shape of a character can be approximated by straight lines, curved lines, arcs, a combination thereof, or the like, using the coordinate data of contour points. If an area where the inside of a contour line overlaps a sub-pixel is greater than or equal to a predetermined area, such a sub-pixel is determined to correspond to a basic portion

10
15
20

representing the skeleton of a character.

Skeleton data contains a character code for identifying the type of a character, the number of strokes constituting a single character, the number of points constituting a single stroke, the line type of a stroke (curved line, straight line, or the like), the coordinates of points constituting a single stroke, and the like. In this case, each stroke is in the form of a line of a certain line type for representing the skeletal shape of a character, and does not have a thickness. If the line type of a stroke is a straight line, the stroke can be approximated by a straight line passing through a plurality of points constituting the stroke using the coordinate data. If the line type of a stroke is a curved line, the stroke can be approximated by a curved line passing through a plurality of points constituting the stroke using the coordinate data. Sub-pixels 11 on a stroke are determined as sub-pixels 12 (Figure 2B) corresponding to the basic portion representing the skeleton of a character.

20

The bitmap data has binary values. Each bit constituting the bitmap data has a value of "1" or "0". A bit having a value of "1" represents a black portion in graphics. A bit having a value of "0" represents a white portion in

a graphic. A basic portion of a graphic corresponds to a core in a graphic. When a graphic is a character, the basic portion is a middle portion of a stroke. In the bitmap data, stroke information is lost. Bits in the bitmap data are associated with the basic portion by inference. The basic portion cannot be inferred only by information of bit $D(x, y)$ of interest. However, the basic portion is inferred based on information of bits neighboring bit D of interest. It is initially determined whether or not each bit constituting the bitmap data is "1", so as to investigate the "1"/"0" arrangement pattern of neighboring bits around the bit of interest. The bit of interest is associated with a pixel. Among the subpixels of the pixel with which the bit of interest is associated, a sub-pixel 12 corresponding to the basic portion is determined according to the arrangement pattern of the neighboring bits.

Figure 15 is a diagram showing a portion of bitmap data representing a graphic. $D(x, y)$ represents a bit of interest. $N(a, b)$ represents bit $D(x+a, y+b)$ around $D(x, y)$. Figure 15 shows eight bits $N(-1, 1)$, $N(0, -1)$, $N(1, -1)$, $N(-1, 0)$, $N(1, 0)$, $N(-1, 1)$, $N(0, 1)$, and $N(1, 1)$ neighboring bit $D(x, y)$ in a vertical, horizontal, or slant direction. These eight neighboring bits are called eight neighbors.

$N(a, b)$ and $D(x, y)$ each has a value of "1" or "0".

Figure 16 is a diagram showing a portion of the display surface of a display device. $P(x, y)$ represents a pixel on the display surface. Bit $D(x, y)$ shown in Figure 15 is associated with pixel $P(x, y)$ when a graphic represented by bitmap data is displayed on a display device. $P(x, y)$ contains three sub-pixels $C(3x, y)$, $C(3x+1, y)$ and $C(3x+2, y)$. When $D(x, y)$ has a value of "1", a sub-pixel corresponding to a basic portion is determined among the three sub-pixels $C(3x, y)$, $C(3x+1, y)$ and $C(3x+2, y)$ according to a definition rule. When $D(x, y)$ has a value of "0", none of the three sub-pixels is determined as a sub-pixel corresponding to the basic portion. Note that although bit $D(x, y)$ shown in Figure 15 is associated with a sub-pixel group Grp shown in Figure 16, the number of sub-pixels contained in a group is not necessarily equal to the number of sub-pixels contained in a pixel. For example, a bit in the bitmap data may be associated with a group Grp' consisting of four sub-pixels shown in Figure 16. The direction of arrangement of sub-pixels in a group is not limited to an X direction. For example, a bit in the bitmap data may be associated with a group Grp'' in which sub-pixels are arranged in the X direction and the Y direction as shown in Figure 16.

Figure 17A shows an example of 8 neighbors of a bit of interest $D(x, y)$ in the bitmap data. Bit $N(a, b)$ having a value of "1" is represented by $N(a, b)$. In Figure 17A,
5 $N(0, -1) = N(1, 1) = 1$, $N(1, 0) = N(0, 1) = N(-1, 1) = N(-1, 0) = 0$, and $N(-1, -1)$ and $N(1, -1)$ represented by "※" has any one of "0" and "1". Figure 17B is a diagram showing a sub-pixel which is associated with a basic portion according to a basic portion definition rule when 8 neighboring bits
10 of bit $D(x, y)$ have values shown in Figure 17A. According to the basic portion definition rule, whether or not each of three sub-pixels contained in pixel $P(x, y)$ is associated with a basic portion is determined based on the arrangement of "0" and "1" of bits $N(a, b)$ around bit $D(x, y)$ associated
15 with pixel $P(x, y)$ as follows. Note that bit $D(x, y)$ is assumed to have a value of "1" below. As shown in Figure 16, pixel $P(x, y)$ on the display surface corresponding to bit $D(x, y)$ contains three sub-pixels $C(3x, y)$, $C(3x+1, y)$ and $C(3x+2, y)$. Among these sub-pixels, a sub-pixel having a value of
20 "1" in Figure 17B is associated with a basic portion, while sub-pixels having a value of "0" are not associated with a basic portion. Specifically, sub-pixel $C(3x+2, y)$ is associated with a basic portion, while $C(3x, y)$ and $C(3x+1, y)$ are not associated with a basic portion. For example,

in the bitmap data of Figure 17A, a stroke is inferred to be a curved line (dashed line 50 in Figure 17A) which passes through areas corresponding to bits $N(0, -1)$, $D(x, y)$, and $N(1, 1)$. Such a curved line is considered to pass through the right-hand side of an area corresponding to bit $D(x, y)$. Therefore, in Figure 17B, sub-pixel $C(3x+2, y)$ on the right-hand side of pixel $P(x, y)$ corresponding to bit $D(x, y)$ is associated with a basic portion.

When a sub-pixel 12 corresponding to the basic portion representing the skeleton of a character is determined, the color element levels of the sub-pixel 12 and a sub-pixel 13 neighboring the sub-pixel 12 are determined. For example, when a sub-pixel 12 (hatched in Figure 2B), which is located at the middle of three sub-pixels 11 (Figure 2A) constituting a pixel 10, is determined to correspond to a basic portion, the color element level of the sub-pixel 12 corresponding to the basic portion is set to be "7" which is the maximum level. The color element levels of sub-pixels 13 which neighbor the sub-pixel 12 corresponding to the basic portion and are determined not to correspond to the basic portion, are set to be stepwise decreased, e.g., "5", "2", and "1" with an increase in the distance from the sub-pixel 12 corresponding to the basic

portion. The color element level of sub-pixels 14, which are located at a distance of four pixels from the sub-pixel 12 corresponding to the basic portion, is set to be "0" which is intended to represent a background.

5

Note that when a sub-pixel 13, which does not correspond to a basic portion, neighbors a plurality of sub-pixels 12 corresponding to a basic portion, the color element level of the sub-pixel 13 can take a plurality of values depending on the distance from the sub-pixels 12. In this case, the color element level of the sub-pixel 13 is set to be the greatest value.

The color element level of each sub-pixel is converted to a luminance level according to a correspondence between color element levels and luminance levels. In Figure 2B, the luminance level of the sub-pixel 12 corresponding to the basic portion is set to be "0". The luminance level of a sub-pixel having a color element level of "5", which neighbors the sub-pixel 12, is set to be "73". The luminance level of a sub-pixel having a color element level of "2" is set to be "182". The luminance level of a sub-pixel having a color element level of "1" is set to be "219". The luminance level of the sub-pixel 14, whose color element level is set

to "0" as a background, is set to be "255".

In this embodiment, a luminance level is determined as follows. As shown in Figure 2C, a sub-pixel(s) corresponding to a basic portion (i.e., a sub-pixel(s) to which a basic portion is assigned) is extracted from $M+2 \times N$ sub-pixels (M sub-pixels 16 contained in a pixel (pixel of interest) 15 whose luminance level is to be determined and N sub-pixels 17 neighboring on each side of pixel 15). Based on the arrangement pattern of the extracted sub-pixel(s), the luminance levels (i.e., pixel value) of M sub-pixels 16 contained in the pixel 15 of interest are determined.

Figure 3 is a diagram showing an example of the pixel value table 5e. In Figure 3 and Figures 4 to 7, it is assumed that the number (M) of the sub-pixels 16 contained in the pixel 15 of interest shown in Figure 2C is 3 ($M=3$), and the number (N) of the sub-pixels 17 on each side of the pixel 15 is 3 ($N=3$). Note that the number N of the above-described pixels is typically the same as the number of elements in a correction pattern ($N=3$ in Figure 10). The left-hand side of Figure 3 shows an arrangement pattern of 9 sub-pixels contained in 3 pixels (the pixel 15 of interest and pixels on the both sides thereof) which are arranged in the same

direction as that of the arrangement of the sub-pixels. An arrangement pattern contains a plurality of elements. The value of each element is determined by the control section 20 depending on whether or not a basic portion is assigned to a corresponding sub-pixel of the subpixels 16 and the subpixels 17. In the figures, element "0" indicates that a basic portion is not assigned to a sub-pixel relating to the element; element "1" indicates that a basic portion is assigned to a sub-pixel relating to the element; and element "x" indicates that either a basic portion is assigned to a sub-pixel relating to the element or a basic portion is not assigned to a sub-pixel relating to the element. The right-hand side of Figure 3 shows the luminance value of each sub-pixel (R, G, B) contained in a pixel of interest corresponding to the arrangement pattern on the left side of Figure 3.

The pixel value of a pixel is determined using the pixel value table 5e indicating a correspondence between the arrangement pattern of sub-pixels corresponding to the basic portion of a character and the luminance values of sub-pixels contained in a pixel whose pixel value (the luminance levels of sub-pixels) is to be determined. The above-described correspondence indicated by the pixel value

table 5e is predetermined.

For example, it is assumed that the arrangement pattern of sub-pixels corresponding to a basic portion is "x10 000 01x". For example, when the correspondence indicated by the pixel value table 5e has been determined using the correction pattern 1 shown in Figure 10, the arrangement of the color element levels is "x75, 212, 57x". The color element levels (2, 1, 2) of sub-pixels (R, G, B) contained in a pixel of interest whose pixel value is to be determined are converted to luminance levels (182, 219, 182) when the correspondence indicated by the pixel value table 5e has been determined using the correspondence between color element levels and luminance levels shown in Figure 11. Therefore, in the pixel value table 5e of Figure 3, the arrangement pattern "x10 000 01x" of the sub-pixels corresponding to a basic portion previously corresponds to the pixel values (182, 219, 182) of the pixel. The other arrangement patterns previously correspond to the pixel values of pixels.

Note that when a pixel of interest is located at an end of a display device, no neighboring pixel is present at one side of the pixel of interest. In this case, another

process is performed. For example, when a pixel of interest is located at an end of a display device, the luminance level of the pixel of interest may be inevitably set to (255, 255, 255).

5

Figure 4 is a diagram showing another example of the pixel value table 5e. The left-hand side of Figure 4 shows an arrangement pattern of 9 sub-pixels contained in 3 pixels which are arranged in the same direction as that of the arrangement of the sub-pixels. The right-hand side of Figure 4 shows the luminance value of each sub-pixel (R, G, B) contained in a pixel of interest corresponding to the arrangement pattern on the left side of Figure 4.

15 The pixel value of a pixel is determined using the pixel value table 5e indicating a correspondence between the arrangement pattern of sub-pixels corresponding to the basic portion of a character and the luminance values of sub-pixels contained in a pixel whose pixel value is to be determined.

20

For example, it is assumed that the arrangement pattern of sub-pixels corresponding to a basic portion is "000 001 000". For example, when the correspondence

indicated by the pixel value table 5e has been determined using the correction pattern 1 shown in Figure 10, the arrangement of the color element levels is "001, 257, 521". The color element levels (2, 5, 7) of sub-pixels (R, G, B) contained in a pixel of interest whose pixel value is to be determined are converted to luminance levels (182, 73, 0) when the correspondence indicated by the pixel value table 5e has been determined using the correspondence between color element levels and luminance levels shown in Figure 11. Therefore, in the pixel value table 5e of Figure 4, the arrangement pattern "000 001 000" of the sub-pixels corresponding to a basic portion previously corresponds to the pixel values (182, 73, 0) of the pixel. The other arrangement patterns previously correspond to the pixel values of pixels.

As described above, the correspondence between the arrangement pattern of sub-pixels corresponding to a basic portion and the luminance values of the sub-pixels is predetermined in the pixel value table 5e. Therefore, when sub-pixels corresponding to a basic portion are near each other, the pixel values of pixels present between strokes can be controlled by adjusting the luminance values of sub-pixels corresponding to the arrangement pattern.

Therefore, it is possible to prevent black pixels from filling between strokes of a character, i.e., space within the character is diminished, or the like. Thus, the quality of display can be improved.

5

Figure 5 is a diagram showing another example of the pixel value table 5e. In this example, a basic portion is moved in order to prevent space within a character from being diminished. The left-hand side of Figure 5 shows an arrangement pattern of 9 sub-pixels contained in 3 pixels which are arranged in the same direction as that of the arrangement of the sub-pixels. The middle of Figure 5 shows an arrangement pattern of sub-pixels in which the value of an element relating to a sub-pixel to the left-handed side of the arrangement pattern to which a basic portion is assigned, is replaced with the value "0" of an element relating to a sub-pixel located at the middle of three sub-pixels contained in each pixel (a sub-pixel neighboring the sub-pixel to which a basic portion is assigned). The right-hand side of Figure 5 shows the luminance value of each sub-pixel (R, G, B) contained in a pixel of interest, corresponding to each arrangement pattern in the middle of Figure 5.

10

15

20

The pixel value of a pixel is determined using the pixel value table 5e indicating a correspondence between the arrangement pattern of sub-pixels corresponding to the basic portion of a character and the luminance values of sub-pixels contained in a pixel whose pixel value is to be
5 determined.

For example, it is assumed that the arrangement pattern of sub-pixels corresponding to a basic portion is
10 "000 001 000". By replacement of the basic portion, the arrangement of the sub-pixels is changed to "000 010 000". In this case, when the correspondence indicated by the pixel value table 5e has been determined using the correction pattern 1 shown in Figure 10, the arrangement of the color
15 element levels is "012, 575, 210". The color element levels (5, 7, 5) of sub-pixels (R, G, B) contained in a pixel of interest whose pixel value is to be determined are converted to luminance levels (73, 0, 73) when the correspondence indicated by the pixel value table 5e has been determined
20 using the correspondence between color element levels and luminance levels shown in Figure 11. Therefore, in the pixel value table 5e of Figure 5, the arrangement pattern "000 001 000" of the sub-pixels corresponding to a basic portion previously corresponds to the pixel values (73, 0, 73) of

the pixel. The other arrangement patterns previously correspond to the pixel values of pixels.

Figure 6 is a diagram showing another example of the pixel value table 5e. In Figure 6, a duplicate of a basic portion is provided on the left side of the basic portion to thicken the line width of a character (multiplexing). The left-hand side of Figure 6 shows an arrangement pattern of 9 sub-pixels contained in 3 pixels which are arranged in the same direction as that of the arrangement of the sub-pixels. The middle of Figure 6 shows an arrangement pattern, in which in addition to a sub-pixel corresponding to a basic portion, a sub-pixel neighboring to the left-handed side of that pixel is changed to correspond to a basic portion where the value of a corresponding element of the arrangement pattern is changed "0" to "1". The right-hand side of Figure 6 shows the luminance value of each sub-pixel (R, G, B) contained in a pixel of interest, corresponding to each arrangement pattern in the middle of Figure 6.

20

The pixel value of a pixel is determined using the pixel value table 5e indicating a correspondence between the arrangement pattern of sub-pixels corresponding to the basic portion of a character and the luminance values of

sub-pixels contained in a pixel whose pixel value to be determined.

For example, it is assumed that the arrangement of sub-pixels corresponding to a basic portion is "x10 000 01x x". By providing a duplicate of the basic portion to the left-hand side of the sub-pixel, the arrangement of the sub-pixels is changed to "x10 010 11x x". In this case, when the correspondence indicated by the pixel value table 5e has been determined using the correction pattern 1 shown in Figure 10, the arrangement of the color element levels is "x75, 225, 77x, x". The color element levels (2, 2, 5) of sub-pixels (R, G, B) contained in a pixel of interest whose pixel value is to be determined are converted to luminance levels (182, 182, 73) when the correspondence indicated by the pixel value table 5e has been determined using the correspondence between color element levels and luminance levels shown in Figure 11. Therefore, in the pixel value table 5e of Figure 6, the arrangement pattern "x10 000 01x x" of the sub-pixels corresponding to a basic portion previously corresponds to the pixel values (182, 182, 73) of the pixel. The other arrangement patterns previously correspond to the pixel values of pixels.

Figure 7 is a diagram showing another example of the pixel value table 5e. Figure 7 shows a correspondence between the arrangement of sub-pixels corresponding to a basic portion and the pixel values (R, G, B) of pixels, where the color of a background is orange, i.e., (R, G, B) = (255, 127, 0). The left-hand side of Figure 7 shows an arrangement pattern of 9 sub-pixels contained in 3 pixels which are arranged in the same direction as that of the arrangement of the sub-pixels. The right-hand side of Figure 7 shows the luminance value of each sub-pixel (R, G, B) contained in a pixel of interest, corresponding to each arrangement pattern in the middle of Figure 7.

The pixel value of a pixel is determined using the pixel value table 5e indicating a correspondence between the arrangement of sub-pixels corresponding to the basic portion of a character and the luminance values of sub-pixels contained in a pixel whose pixel value to be determined.

For example, it is assumed that the arrangement of sub-pixels corresponding to a basic portion is "000 000 000". In this case, there is no sub-pixel corresponding to the basic portion of a character. A pixel whose pixel value is to be determined corresponds to a background. Therefore,

the luminance value of (R, G, B) is (255, 127, 0).

The color element levels of sub-pixels neighboring a basic portion, which are stepwise changed, are adjusted according to the distribution of luminance in the background color. For example, it is assumed that the arrangement of sub-pixels corresponding to the basic portion is "000 001 000". When the background color is white, the arrangement of color element levels is "001, 257, 521" as shown in Figure 4.

10 The color element levels (2, 5, 7) of sub-pixels (R, G, B) contained in a pixel of interest whose pixel value is to be determined are converted to luminance levels (182, 73, 0). In contrast, when the background color is orange, the ratio of the luminance levels (R, G, B) is (1, 1/2, 0).

15 Therefore, the color element levels (2, 5, 7) of the sub-pixels (R, G, B) contained in the pixel of interest whose pixel value is to be determined are converted to luminance levels (182, 36, 0) where the level of G is adjusted to $73 \times 1/2 \approx 36$. Thus, in the pixel value table 5e of Figure 7, the arrangement

20 pattern "000 001 000" of the sub-pixels corresponding to the basic portion previously corresponds to the adjusted pixel values (182, 36, 0) of the pixel. The other arrangement patterns previously correspond to the pixel values of pixels.

A correspondence between the arrangement of sub-pixels and the pixel value of a pixel to be set for any character color and background color, can be adjusted according to the character color and background color based on the pixel value table 5e indicating a correspondence for a basic color combination, i.e., black characters in a white background as shown in Figures 3 and 4. For each color combination, the pixel value of a pixel can be determined according to a pixel value table 5e as shown in Figure 7.

10

For each combination of a character cooler and a background color, a pixel value table as shown in Figure 7 may be prepared, or the values of a pixel value table as shown in Figures 3 and 4 may be adjusted so as to determine a correspondence between the arrangement of sub-pixels and a pixel value. When there are a number of combinations of a character color and a background color, similar colors may be grouped and pixel value tables indicating a correspondence are prepared for respective representative colors. In this case, pixel value tables indicating a correspondence may be adjusted according to the size of a difference between the character and background colors and the representative color. For example, the sum of squares of differences between each color (R, G, B), the sum of absolute

15

20

differences between each color (R, G, B), or the like, can be used as an indicator for determining the size of a color difference. A difference in color element level in color space (e.g., YUV space, Lab space, or the like) based on visual characteristics may be used as an indicator for determining a color difference. If a difference between a representative color assigned to the above-described pixel value table indicating a correspondence and a color specified in displaying a character is less than or equal to a predetermined threshold, the specified color is determined as a color belonging to a group including the representative color and the pixel value table can be used to determine the pixel value of a pixel.

The above-described pixel value table 5e indicating a correspondence between the arrangement of sub-pixels and the pixel value of a pixel has $2^{(M+2 \times N)}$ entries of arrangement combinations of sub-pixels, i.e., the combinations of the presence or absence ("1" or "0") of a basic portion in $(M+2 \times N)$ sub-pixels. For example, if $M=N=3$, the number of entries is 512. As shown in Figure 10, however, correction patterns are predetermined, in which the color element levels of sub-pixels neighboring a sub-pixel corresponding to a basic portion are stepwise changed. Therefore, the sequence of

the luminance values of sub-pixels is limited. When correction patterns overlap in a sub-pixel, the larger color element level is set in the sub-pixel. Therefore, the number of pixel values obtained by combinations of sub-pixels is

5 $5 \times N + 8$ where $M=3$. Therefore, if $M=N=3$, the number of pixel values is 23. By assigning 23 indexes to 512 arrangement patterns, a data capacity for storing pixel values actually prepared can be reduced as compared to when 24-bit full color data is prepared in a table where each of (R, G, B) has a

10 length of 8 bit (=0 to 255). Note that the number of combinations is not limited to 23 when pixel values are set more precisely.

As described above, a table indicating a

15 correspondence between the arrangement pattern and luminance levels of sub-pixels in a direction along which R, G, and B are arranged, is used to determine the luminance levels of sub-pixels contained in a pixel of interest. The present invention is not so limited. Alternatively, the luminance

20 level of sub-pixels in a pixel of interest may be determined based on an arrangement pattern of sub-pixels in a direction perpendicular (or oblique) to the direction along which R, G, and B are arranged, for example. In this case, a table indicating a correspondence between the arrangement pattern

and luminance levels of sub-pixels arranged in the perpendicular (or oblique) direction, is used.

Figure 8 is a flowchart indicating a process flow of the display program 41b (Figure 1) when the character shape data 5b is skeleton data.

In step S101, a character code and a character size are input through the input device 7. For example, when a Kanji character "木" is displayed on the display device 10, 4458 (JIS KUTEN code, 44th section and 58th point) is input as a character code. The character size is represented by the number of dots in a horizontal direction and the number of dots in a vertical direction, e.g., 20 dots x 20 dots, for example.

In step S102, skeleton data corresponding to the input character code is read from the character shape data 5b in the auxiliary memory apparatus 40 and is then stored in the main memory 4 of the control apparatus 20. This skeleton data contains a character code for identifying the type of a character, the number of strokes constituting a single character, the number of points constituting a single stroke, the line type of a stroke, the coordinates of points

constituting a single stroke, and the like.

In step S103, the coordinate data of points constituting each stroke is scaled according to the character size input through the input device 7. This scaling converts the coordinate data in the skeleton data defined in a predetermined coordinate system to a real pixel coordinate system for the display device 10. In this case, the scaling is performed by considering the arrangement of sub-pixels. As shown in Figure 2A, for example, one pixel 10 comprises three sub-pixels 11 arranged in an X direction. When a character size is 20 dots \times 20 dots, the coordinate data of the skeleton data is scaled into data of 60(=20 \times 3) pixels \times 20 pixels.

15

In step S104, the coordinate data of points constituting a stroke is obtained.

In step S105, it is determined whether the type of the stroke is a straight line or a curved line from the line type of the stroke contained in the skeleton data. When the type of the stroke is a straight line, the process goes to step S106. When the type of the stroke is a curved line, but not a straight line, the process goes to step S107.

20

In step S106, the points constituting the stroke are linked with straight lines, and sub-pixels on the straight lines are defined as the basic portion representing the skeleton of a character. In step S107, the coordinate data of the points constituting the stroke is approximated by curved lines, and sub-pixels positioned on the curved lines are defined as the basic portion representing the skeleton of a character.

10

In step S108, it is determined whether or not all strokes contained in a character have been processed. If "Yes", the process goes to step S109. If "No", the process returns to step S103 and is continued.

15

In step S109, the arrangement pattern of the sub-pixels in a pixel of interest whose pixel value (the luminance levels of sub-pixels) is to be determined and its neighboring pixels, is determined.

20

In step S110, a pixel value of the pixel of interest corresponding to the arrangement pattern of the sub-pixels determined in step S109 is determined as the luminance levels of sub-pixels contained in the pixel of interest according

to the pixel value table 5e indicating a correspondence between the arrangement pattern of sub-pixels corresponding to a basic portion and the pixel value (the luminance levels of sub-pixels) of a pixel.

5

In step S111, luminance data indicating the luminance levels of the sub-pixels set in step S110 is transferred to the display device 3.

10

As described above, the luminance level can be adjusted on a sub-pixel-by-sub-pixel basis based on the arrangement of sub-pixels corresponding to a basic portion for the purpose of displaying a character on the display device 3. In the above-described embodiment, sub-pixels corresponding to the basic portion indicating the skeleton of a character are obtained from skeleton data. Alternatively, such sub-pixels may be obtained from outline data, bitmap data, or the like by a predetermined process. Alternatively, the pattern of the basic portion may be previously stored as character shape data in the auxiliary memory apparatus 40 and may be read as required.

15

20

INDUSTRIAL APPLICABILITY

As described above, according to the present invention, when a character is displayed with a high resolution on a display section capable of displaying color, a luminance level to be displayed on the display section can be obtained directly by converting the arrangement pattern of sub-pixels corresponding to the basic portion representing the skeleton of a character. Therefore, the character display process can be performed at a higher rate and a working memory area for performing the character display process can be reduced. As a result, character display processing can be performed at a higher rate and the hardware cost can be reduced.

15

According to the present invention, when character strokes are close to each other, the positions of sub-pixels corresponding to the basic portion representing the skeleton of a character can be adjusted to easily prevent deformation of a character. Further, in addition to a sub-pixel corresponding to the basic portion representing the skeleton of a character, its neighboring sub-pixels are allowed to represent the basic portion, thereby making it possible to easily increase the line width of the character.

20

Any color may be assigned to a character to be displayed and a background. In this case, by changing a correspondence between the arrangement of sub-pixels and the luminance levels of sub-pixels according to the character color and the background color, it is possible to provide a character display in which the shape of a character is retained and a high level of visibility is achieved irrespective of a color combination.

10

Similar combinations of a character color and a background color may be grouped. In this case, correspondences between the arrangement pattern of sub-pixels corresponding to a basic portion and the pixel value of a pixel for a group of color combinations can be merged into a correspondence for a representative color combination. Therefore, a data amount required for a correspondence table between the arrangement pattern of sub-pixels corresponding to a basic portion and the pixel value of a pixel can be reduced.

20

Various other modifications will be apparent to and can be readily made by those skilled in the art without departing from the scope and spirit of this invention.

Accordingly, it is not intended that the scope of the claims appended hereto be limited to the description as set forth herein, but rather that the claims be broadly construed.

CLAIMS

1. A character display apparatus, comprising:

a display device comprising a plurality of pixels;

5 and

a control section for controlling the display device,

wherein each of the plurality of pixels comprises
a plurality of sub-pixels arranged in a predetermined
direction, and at least one of a plurality of color elements

10 is assigned to each of the plurality of sub-pixel;

the control section determines at least one sub-pixel,
to which a basic portion indicating a skeleton of a character
is assigned, among the plurality of sub-pixels in the display
device, based on character shape data indicating character
15 shapes;

a first pixel of the plurality of pixels comprises
a plurality of first sub-pixels;

at least one pixel neighboring the first pixel
comprises a plurality of second sub-pixels;

20 the control section determines an arrangement
pattern containing a plurality of elements, wherein a value
of each of the plurality of elements is determined depending
on whether or not the basic portion is assigned to a
corresponding sub-pixel of the plurality of the first

sub-pixels and the plurality of the second sub-pixels; and
the control section determines a luminance level of
the first pixel based on the arrangement pattern.

- 5 2. An apparatus according to claim 1, wherein the plurality
of elements include a first element and a second element
neighboring the first element;

 a value of the first element indicates that the basic
portion is assigned to a sub-pixel relating to the first
10 element;

 a value of the second element indicates that the basic
portion is not assigned to a sub-pixel relating to the second
element; and

 the control section determines the luminance level
15 of the first pixel based on another arrangement pattern which
is modified from said arrangement pattern such that a value
of the first element is interchanged with a value of the
second element.

- 20 3. An apparatus according to claim 1, wherein the plurality
of elements include a first element and a second element
neighboring the first element;

 a value of the first element indicates that the basic
portion is assigned to a sub-pixel relating to the first

element;

a value of the second element indicates that the basic portion is not assigned to a sub-pixel relating to the second element; and

5 the control section determines the luminance level of the first pixel based on another arrangement pattern which is modified from said arrangement pattern such that a value of the second element is changed to indicate that the basic pattern is assigned to the sub-pixel relating to the second
10 element.

4. An apparatus according to claim 1, wherein the control section determines the luminance level of the first pixel based on a combination of a color of the character and a
15 background color of the character and the arrangement pattern.

5. An apparatus according to claim 1, wherein the control section compares a combination of a color of the character and a background color of the character with a combination
20 of a predetermined character color and a predetermined background color, and determines the luminance level of the first pixel based on a result of the comparison and the arrangement pattern.

6. A method for displaying a character on a character display apparatus, wherein

the character display apparatus comprises:

5 a display device comprising a plurality of pixels;

and

a control section for controlling the display device,

wherein each of the plurality of pixels comprises
a plurality of sub-pixels arranged in a predetermined
10 direction, and at least one of a plurality of color elements
is assigned to each of the plurality of sub-pixel;

a first pixel of the plurality of pixels comprises
a plurality of first sub-pixels; and

at least one pixel neighboring the first pixel
15 comprises a plurality of second sub-pixels,

the method comprises the steps of:

determining at least one sub-pixel, to which a basic
portion indicating a skeleton of a character is assigned,
among the plurality of sub-pixels in the display device,
20 based on character shape data indicating character shapes;

determining an arrangement pattern containing a
plurality of elements, wherein a value of each of the plurality
of elements is determined depending on whether or not the
basic portion is assigned to a corresponding sub-pixel of

the plurality of the first sub-pixels and the plurality of the second sub-pixels; and

determining a luminance level of the first pixel based on the arrangement pattern.

5

7. A program for causing a character display apparatus to execute a character display process, wherein

the character display apparatus comprises:

a display device comprising a plurality of pixels;

10 and

a control section for controlling the display device,

wherein each of the plurality of pixels comprises a plurality of sub-pixels arranged in a predetermined direction, and at least one of a plurality of color elements

15 is assigned to each of the plurality of sub-pixel;

a first pixel of the plurality of pixels comprises a plurality of first sub-pixels; and

at least one pixel neighboring the first pixel comprises a plurality of second sub-pixels, and

20 the character display process comprises the steps of:

determining at least one sub-pixel, to which a basic portion indicating a skeleton of a character is assigned, among the plurality of sub-pixels in the display device, based on character shape data indicating character shapes;

determining an arrangement pattern containing a plurality of elements, wherein a value of each of the plurality of elements is determined depending on whether or not the basic portion is assigned to a corresponding sub-pixel of the plurality of the first sub-pixels and the plurality of the second sub-pixels; and

determining a luminance level of the first pixel based on the arrangement pattern.

10 8. A recording medium storing a program for causing a character display apparatus to execute a character display process, wherein the recording medium is readable by the character display apparatus,

the character display apparatus comprises:

15 a display device comprising a plurality of pixels;
and

a control section for controlling the display device,
wherein each of the plurality of pixels comprises a plurality of sub-pixels arranged in a predetermined direction, and at least one of a plurality of color elements is assigned to each of the plurality of sub-pixel;

20 a first pixel of the plurality of pixels comprises a plurality of first sub-pixels; and

at least one pixel neighboring the first pixel

comprises a plurality of second sub-pixels, and

the character display process comprises the steps of:

determining at least one sub-pixel, to which a basic
portion indicating a skeleton of a character is assigned,
5 among the plurality of sub-pixels in the display device,
based on character shape data indicating character shapes;

determining an arrangement pattern containing a
plurality of elements, wherein a value of each of the plurality
of elements is determined depending on whether or not the
10 basic portion is assigned to a corresponding sub-pixel of
the plurality of the first sub-pixels and the plurality of
the second sub-pixels; and

determining a luminance level of the first pixel based
on the arrangement pattern.
